

**ISOMETRUS (REDDYANUS) KURKAI SP. N. FROM INDONESIA
(SCORPIONES, BUTHIDAE)**

František Kovařík

U Botiče 1/1389, CZ-140 00 Praha 4, Czech Republic

Received December 2, 1996

Accepted February 14, 1997

Abstract. *Isometrus (Reddyanus) kurkai* sp. n. is described from Indonesia. It is compared with all species of the subgenus *Reddyanus* VACHON, 1972, from which it differs in having only two granules on the subaculear tooth. The number of granules on the subaculear tooth divides the species of the subgenus *Reddyanus* into four groups. A checklist of all species of the genus *Isometrus* HEMPRICH & EHRENBURG, 1828, is included.

■ Taxonomy, description, new species, Scorpiones, Buthidae, *Isometrus*, *Reddyanus*, *I. kurkai* sp. n., Indonesia.

***Isometrus (Reddyanus) kurkai* sp. n. (Figs 1-5, 11, Tab. 1)**

Type material. Holotype - female preserved in alcohol, labelled: Java, Tigenter, Mündung, 6.VIII.1969, leg. R. Schenkel, in the collection of the Naturhistorisches Museum Basel, Switzerland. This specimen was examined by Prof. Max Vachon in 1975 (No. VA- 491) and identified by him as *Isometrus (Reddyanus)* sp. ?.

Etymology. Named in honor of the arachnologist RNDr. Antonín Kůrka, Curator of Zoology at the National Museum in Prague, who has been very helpful to me.

Description. The total length is 23.5 mm. The habitus is shown in Fig. 11. Measurements of the carapace, telson, segments of the metasoma and of the pedipalps, and numbers of pectinal teeth are given in Table 1. There are 13 pectinal teeth. For the position and distribution of trichobothria on the pedipalps see Figs 2-4.

The base color is yellow, with well marked black reticulation.

The chelicerae are reticulated, more densely so on the anterior margin. Movable fingers of the chelicerae bear a large black spot.

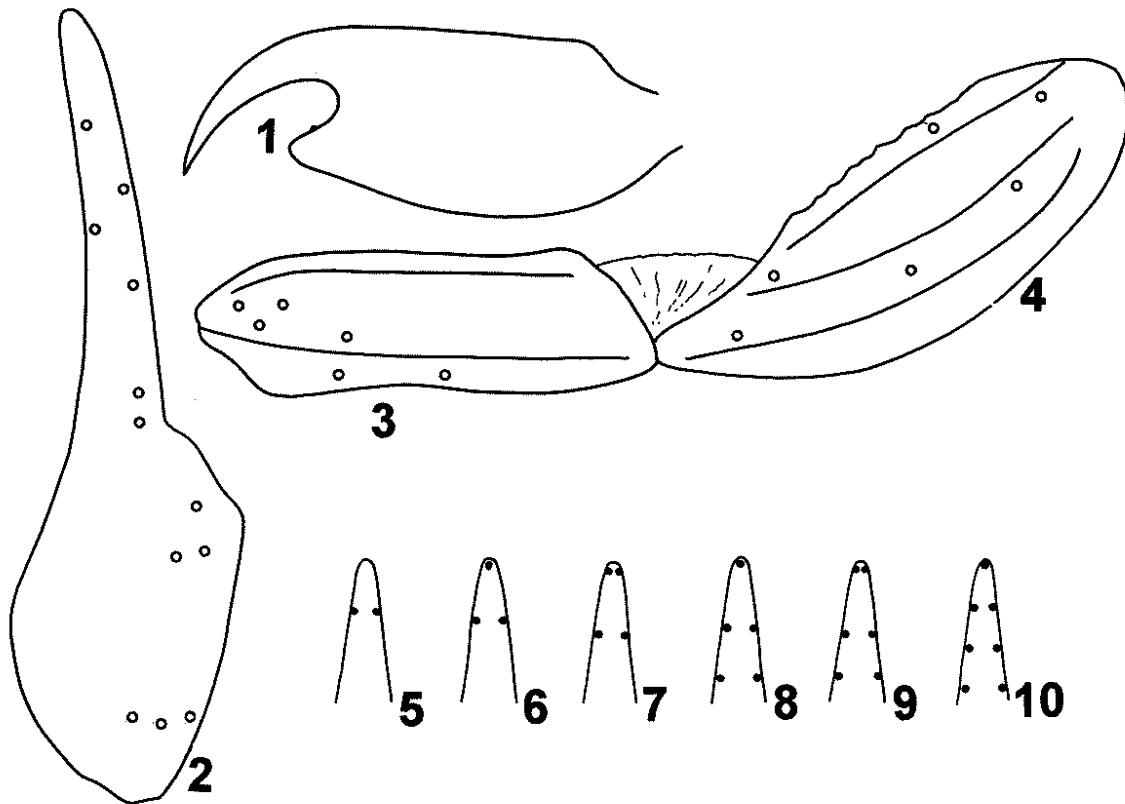

The carapace lacks keels but bears large granules. The color pattern is spotted. The area in front of the eyes is more densely granulated and dark, similar to the genus *Lychas* and *Isometrus (Reddyanus) zideki* Kovařík, 1994.

The femur of the pedipalps is spotted, with well developed keels. The dorsal surface bears sparse but pronounced granules. The patella also has keels and is spotted, with dark blotches being dominant. The manus is yellow with several isolated dark spots, and the fingers are dark. The movable fingers have six cutting edges with seven such edges on the fixed fingers.

The mesosoma is dorsally spotted, with three dark bands of uneven width, and a medial keel that is yellow along much of its length. Its ventral surface is pale yellow to white with four inconspicuous keels on the seventh segment.

The legs are more spotted dorsally than ventrally.

The metasoma is spotted as well. The anterior halves of the first through fourth segments, the telson, and the anterior third of the fifth segment are yellow, whereas the remaining posterior parts are dark with sparse yellow spots. The aculeus is yellow to reddish brown. The first segment bears 10

Figs 1-10. Figs. 1-5 *Isometrus (Reddyanus) kurkai* sp.n. (holotype). Fig. 1. Telson, Fig. 2. Tibia, Fig. 3. Femur dorsal, Fig. 4. Patella dorsal, Fig. 5. Subaculear tooth. Figs 6-10. Subaculear tooth (schematic presentation). Fig. 6. *I. (R.) zideki* (female, paratype No. 4). Fig. 7. *I. (R.) heimi* (see Vachon 1976: 43, figs 16-17). Fig. 8. *I. (R.) zideki* (male, paratype No. 1). Fig. 9. *I. (R.) besucheti*. Fig. 10. *I. (R.) basilicus* (see Vachon 1976: 94, fig. 49a).

keels, the second through fourth segments eight, and the fifth segment bears five. All keels are well developed and consist of fine granules of the same size. However, the dorsolateral keels terminate in a slightly larger granule. There are two ventral keels on the first through fourth segments and one ventral keel on the fifth segment. The subaculear tooth has two granules in a row (Fig. 5).

Affinities. *I. (R.) kurkai* sp. n. differs from all other species of the subgenus *Reddyanus* in having only two granules on the subaculear tooth (Figs 5-10). This number of granules is common in species of the nominotypical subgenus (*Isometrus*), which can however, be easily differentiated from the subgenus *Reddyanus* on only six cutting edges of fixed fingers of the pedipalps (figs 64-67 in Vachon 1982: 100) and by the positions of the trichobothria dt, db and et, est on fixed fingers of the pedipalps (Fig. 2 and figs 13-14 in Vachon 1972: 176).

The geographically closest species is *I. (R.) zideki* from the Cameron Highlands in Malaysia (Kovařík 1994: 195). *I. (R.) zideki* shares with *I. (R.) kurkai* sp. n. pronounced ventral keels on the metasomal segments (figs 10 and 12 in Kovařík 1994: 200), but differs in having three and often up to five granules on the subaculear tooth (Figs 5, 6, 8), in the coloration of the metasomal segments (the first three yellow and the last two dark), and a greater width of the manus of pedipalps.

ACKNOWLEDGEMENTS

I thank Matt E. Braunwalder and Ambros Hänggi of the Naturhistorisches Museum Basel, Switzerland, for lending me the specimen; Matúš Kocián of Prague for the habitus drawing of *Isometrus (R.) kurkai* sp. n.; and Jiří Zídek of Socorro (USA) for helping with the language.
